

TECHNICAL NOTE

Real Economic Activity Indicators and Indonesia's Recent GDP Developments

Prepared by

Department of Economics, Faculty of Economics and Business, Universitas Gadjah Mada¹

This note examines the consistency between Indonesia's recent Gross Domestic Product (GDP) acceleration and selected independent indicators of real activity and financial-market conditions. The exercise is descriptive and diagnostic; it does not assess whether official GDP estimates are correct or incorrect. The findings point to a weakening in household-consumption indicators after 2025Q2, while investment indicators provide partial support, though not enough to match the full magnitude of the official investment acceleration. Financial-market reactions are mixed and do not point to a uniformly positive interpretation of the post-2025Q2 GDP releases.

Official GDP data show stronger year-on-year (y-o-y) growth after 2025Q2. The growth rose from around 5 percent to 5.61 percent by 2026Q1 but this increase was not evenly spread across all GDP components. Household consumption, investment or gross fixed capital formation (GFCF), and government consumption rose sharply. In contrast, exports weakened after 2025Q2, while imports remained volatile and declined slightly. Since imports reduce GDP, the external sector does not appear to be the main source of stronger growth.

■ **FIGURE 1**

GDP year on year (y-o-y) growth by selected expenditure component

Notes: The figure shows year on year (y-o-y) log growth of selected expenditure-side GDP components. The vertical dotted line marks 2025Q2.

The component-level data suggests that the post-2025Q2 strengthening came mainly from domestic demand, which is why our analysis focuses on household consumption and GFCF. Average quarter-to-quarter value changes increase for GDP, household consumption, GFCF, and especially government consumption. At the same time, exports decline sharply and imports increase. Because government consumption is more directly linked to fiscal spending, the key question for broader economic activity is whether the two main private-demand components—household consumption and GFCF—are also supported by related indicators. Household consumption is important because it is the largest expenditure-side component of GDP, while GFCF is important because it captures investment activity and is central to the interpretation of future productive capacity.

■ **TABLE 1** Component-level shift in official GDP components (IDR billion)

Component	Pre-2025Q2 mean	Post-2025Q2 mean	Shift	Evidence
GDP	37,625.3	46,126.2	+8,501.0	Strong increase
Household consumption	20,500.3	32,521.5	+12,021.2	Strong increase
GFCF	9,559.7	16,181.4	+6,621.7	Moderate increase
Government consumption	602.3	10,262.9	+9,660.6	Strong increase
Exports	12,543.4	2,415.0	-10,128.4	Strong decline
Imports	7,337.5	9,641.8	+2,304.3	Weak increase

Notes: Values are average quarter to quarter (q-t-q) value changes. Imports enter GDP with a negative sign; exports weaken after 2025Q2.

Other than using GDP, real economic activity can also be observed through related household and investment indicators. For household consumption, relevant indicators include retail sales, consumer confidence, vehicle sales, household loans, and credit-demand indicators. For investment, relevant indicators include investment realization, cement consumption, investment loans, capacity utilization, *Purchasing Manufacturing Index* (PMI), and business surveys. These indicators help show whether the stronger GDP numbers are also visible in broader parts of the economy.

The indicator scoreboard shows weaker support for household consumption than for investment. Most household-related indicators deteriorate after 2025Q2. Credit demand for consumption, housing/property loans, credit cards, vehicle-related loans, vehicle sales, housing loans, and consumer confidence all weaken. This suggests limited support for a broad-based strengthening in household consumption. Investment loans and bank-lending survey indicators for investment credit improved, but this may partly reflect the government's Rp200 trillion placements of funds in state-owned banks to strengthen banking liquidity and support credit to the real sector, rather than purely stronger private investment demand (Ministry of Finance of the Republic of Indonesia, 2025a, 2025b). Cement consumption also improved, but this should be read carefully because public capital spending remained weaker in 2025 than in the previous year, creating a possible low-base effect for infrastructure-related indicators. As of September 2025, realized capital spending was Rp173.1 trillion, lower than Rp179.1 trillion in the same period of 2024, and the Ministry of Finance noted the need to accelerate capital spending, including infrastructure development. Moreover, early-2025 capital spending was concentrated in equipment and machinery rather than infrastructure works: as of mid-June 2025, Rp47.8 trillion went to equipment and machinery, compared with Rp8.6 trillion for roads, irrigation, and networks and Rp2.9 trillion for buildings (Ministry of Finance of the Republic of Indonesia, 2025b, 2025c).

■ **TABLE 2** Macroeconomic indicators shift, pre- and post-Q2 2025

Indicators	Shift	Interpretation
Indicators that support or partly support stronger activity		
Investment loans	+5.167	Supports stronger investment financing
BLS investment loans	+3.987	Supports stronger investment-credit demand
Cement consumption	+1.570	Supports construction-related activity
Capacity utilization	+0.038	Small positive signal
Retail sales real	+0.077	Broadly flat household-retail signal
Indicators that do not support stronger activity		
BLS consumption loans	-26.827	Weaker household credit demand
BLS housing/property	-18.520	Weaker housing/property-loan demand
BLS credit card	-10.480	Weaker consumer credit demand
Household motor-vehicle loans	-10.210	Weaker durable-consumption credit
Motor vehicle sales	-5.578	Weaker durable-consumption proxy
Housing loans	-3.506	Weaker housing-credit growth
CCI present	-2.004	Weaker consumer sentiment
CCI expectations	-2.299	Weaker consumer sentiment
Investment realization	-15.749	Does not support stronger realized investment
Working-capital loans	-5.387	Weaker production-financing proxy
Business activity survey	-2.306	Weaker business-cycle signal
Purchasing Managers' Index (PMI)	-1.304	Weaker business-cycle signal

Notes: Values are average year on year (y-o-y) value changes. BLS is Bank Lending Survey and CCI is Consumer Confidence Index. Both surveys are conducted by Bank Indonesia. The S&P Global Indonesia Manufacturing Purchasing Managers' Index measures the performance of the manufacturing sector and is derived from a survey of 400 manufacturing companies.

Against this backdrop, the note proceeds with two external-consistency layers. The first compares official household consumption and GFCF growth with principal component analysis (PCA)-based real-activity indices. The second uses an event study to examine whether domestic financial markets reacted differently to post-2025Q2 GDP announcements. These two layers are complementary: one checks activity data, while the other checks market-based interpretation.

These two layers are used in sequence. The real-activity check is the first and more direct test because GDP components should be broadly reflected in related household and investment indicators. The event study is a second, complementary check: if markets viewed the post-2025Q2 GDP releases as credible positive news, we might expect stronger equity responses, rupiah appreciation, or lower yields. If the market reaction is weak, mixed, or points to rupiah pressure, the market-based consistency signal is more limited.

The PCA and bridge-model exercise gives official GDP data a good benchmark. The best-fit indices are chosen using only data before 2025Q2. This means the indices are selected to match official household consumption and GFCF growth as closely as possible before the period of interest. If the relationship weakens after 2025Q2, this suggests that the recent official acceleration is not fully reflected in related activity indicators.

■ **TABLE 3** Best-fit indicator signal

Component	Best-fit indicator signal	Official post	Implied post	Gap	Interpretation
Household consumption	CCI present; retail sales; motor-vehicle loans; housing loans; vehicle sales	5.202	3.988	+1.214	Weak validation
GFCF	Investment realization; capacity utilization; business activity	5.571	4.403	+1.168	Partial but incomplete validation

Notes: Official and implied post values mean post-2025Q2 y-o-y growth rates in percent. Gap is official minus indicator-implied growth.

The bridge-model results show a gap between official growth and indicator-implied growth.

For household consumption, the best-fit Household Consumption Activity Index (HHAI) implies post-2025Q2 growth of 3.988 percent, below the official figure of 5.202 percent. For GFCF, the best-fit Investment Activity Index (IAI) implies growth of 4.403 percent, below the official figure of 5.571 percent. This means that investment indicators are more supportive than household indicators, but they still do not fully explain the size of the official GFCF acceleration.

■ **FIGURE 2**

Best-fit activity indices and official private-demand growth

Notes: The figure compares official y-o-y growth with the corresponding best-fit PCA-based activity index for two private-demand components: GFCF and household consumption. Left panel shows official household consumption growth and the best-fit HHAI, while right panel shows official GFCF growth and the best-fit IAI. Both activity indices are rescaled to the same mean and standard deviation as the corresponding official growth series for visual comparison. The vertical dotted line marks the candidate break in 2025Q2.

Figure 2 shows that the relationship between official growth and activity indicators weakens after 2025Q2. Before 2025Q2, the best-fit indices broadly track their corresponding official GDP components. After 2025Q2, the pattern becomes less aligned, especially for household consumption. Official household consumption growth rises, while the best-fit HHAI declines. For GFCF, the best-fit IAI improves on average after 2025Q2, but not enough to match the official GFCF acceleration. This suggests that investment indicators provide partial support, while household indicators provide weaker support.

The correlation results confirm that the indices fit the official data well before 2025Q2, but not after. Before 2025Q2, the correlations are high: 0.780 for household consumption and 0.855 for GFCF. After 2025Q2, both correlations turn negative. Since the indices were selected to fit the official data as closely as possible before the break, the post-break deterioration suggests that the recent acceleration is not fully mirrored by independent private-demand indicators.

■ **TABLE 4 Best-fit y-o-y correlation between official growth and activity indices**

Component	Activity index	Period	Obs.	Correlation
Household consumption	Best-fit HHA1	Full sample	17	0.273
Household consumption	Best-fit HHA1	Pre-2025Q2	13	0.780
Household consumption	Best-fit HHA1	Post-2025Q2	4	-0.736
GFCF	Best-fit IAI	Full sample	17	0.715
GFCF	Best-fit IAI	Pre-2025Q2	13	0.855
GFCF	Best-fit IAI	Post-2025Q2	4	-0.728

Notes: The table reports correlations between official y-o-y GDP-component growth and the corresponding best-fit PCA-based activity index. The best-fit HHA1 and IAI are selected to maximize pre-2025Q2 correlation with official household consumption and GFCF growth, respectively. Post-2025Q2 correlations use only four observations and should be interpreted as descriptive evidence of changing co-movement, not formal statistical estimates.

The financial-market event study provides a second, complementary check. It compares market responses to earlier non-COVID GDP announcements with responses to GDP announcements after 2025Q2. The analysis uses daily data for the IDX Composite, BI spot USD/IDR, JISDOR, and 1-year and 10-year government bond yields. A positive exchange-rate return means rupiah depreciation.²

■ **TABLE 5 Summary of event-study evidence**

Market signal	Result	Interpretation
IDX Composite	More positive response	Suggestive, weaker after controls
JISDOR	Depreciation signal	Uncontrolled difference significant; weaker with controls
Bond yields	Small yield changes	Limited market-validation signal
Domestic stress index	Difference = -0.152	No evidence of broad-based stress increase

Notes: The table summarizes the main event-study results comparing market reactions to post-2025Q2 GDP announcements with previous non-COVID GDP announcements. Bond yields refer to 1-year and 10-year government bond yields. The domestic stress index combines equity, exchange rate, and 10-year bond-yield movements; a higher value indicates greater market stress. The results should be interpreted as suggestive evidence because several signals weaken after controlling global and cross-market factors.

Financial-market reactions are mixed. Equity responses are more positive after post-2025Q2 GDP announcements, but the result weakens after controlling for global and cross-market factors.

² JISDOR refers to Bank Indonesia's Jakarta Interbank Spot Dollar Rate, a reference exchange rate for rupiah per US dollar.

This positive IDX response should also be interpreted carefully because the equity market is now more domestically held, with foreign ownership having declined to around 40 percent. A stronger IDX response can therefore happen at the same time as rupiah depreciation if domestic investors support the equity market while foreign investors reduce exposure or broader external pressure weighs on the currency. FX responses point more toward rupiah pressure than confidence-driven appreciation. Bond-yield responses are small and statistically weak. The domestic stress index is slightly lower after post-2025Q2 announcements, but the difference is statistically insignificant.

The evidence points to partial and uneven validation of the recent GDP acceleration.

Household-consumption indicators provide limited support because most household-side indicators weaken after 2025Q2 while official consumption growth rises. GFCF receives relatively more support from investment loans, bank-lending survey investment demand, cement consumption, and capacity utilization, but the signal remains incomplete because investment realization, working-capital loans, PMI, and business activity weaken. These results should not be interpreted as evidence that official GDP estimates are incorrect. Rather, they imply the need for greater transparency and a more component-specific interpretation of recent growth, particularly in distinguishing government-demand channels from a broad-based private-demand expansion led by robust investment and household consumption.

■ ONLINE APPENDIX: Methodological Notes

OA1. PCA-based activity indices

The PCA indices summarize multiple activity indicators into a smaller number of common signals. For household consumption, the index is called the Household Consumption Activity Index, or HHA1. For investment, the index is called the Investment Activity Index, or IA1. The purpose is to avoid relying on any single indicator, since each individual series may be noisy, incomplete, or affected by sector-specific factors. Instead, the PCA index extracts the common movement across a set of related indicators.

The indicators are first made comparable before PCA is applied. Monthly indicators are converted to quarterly frequency using aggregation rules that match the nature of each series. Survey and diffusion indicators are averaged within the quarter; flow variables such as sales, cement consumption, or investment realization are summed; and stock variables such as loans are converted using the end-of-quarter value. Where appropriate, variables are transformed into y-o-y log growth rates. The transformed indicators are then standardized to have mean zero and unit variance, so that variables measured in different units can enter the PCA on a comparable basis.

Principal component analysis extracts common variation across indicators. In simple terms, PCA searches for weighted combinations of indicators that explain the largest share of their joint movement. The first principal component, PC1, captures the largest common variation. However, the most relevant signal for official GDP components is not always PC1. PC1 may capture a broad cycle, while PC2 or PC3 may capture more specific information related to household consumption or investment. For this reason, the exercise allows the best-fit index to be selected from PC1, PC2, or PC3.

The best-fit index is selected using only the pre-2025Q2 sample. For each GDP component, the procedure searches across eligible indicator subsets and extracts PC1, PC2, and PC3. It then selects the subset-PC combination with the highest absolute correlation with official y-o-y component growth before 2025Q2:

$$(S^*, k^*) = \arg \max_{S, k} |\text{Corr}(y_t, PC_{k,t}^S)|, t < 2025Q2.$$

Here, S denotes an eligible subset of indicators, $k \in \{1, 2, 3\}$ denotes the selected principal component, y_t is official y-o-y component growth, and $PC_{k,t}^S$ is the k -th principal component extracted from subset S .

This selection rule gives the official data a favorable benchmark. The index is deliberately chosen to fit the official GDP component series as closely as possible before the candidate break. Therefore, the post-2025Q2 comparison is not biased against the official data. If the selected index still fails to match the post-break acceleration, the evidence for external validation becomes weaker.

The selected best-fit indicators differ between household consumption and GFCF. For household consumption, the selected index is PC3 based on CCI present, real retail sales, household motor-vehicle loans, housing loans, and motor-vehicle sales. For GFCF, the selected index is PC2 based on investment realization, capacity utilization, and business activity.

OA2. Bridge-model gaps

The bridge model translates activity-index movements into indicator-implied GDP-component growth. PCA indices are useful for summarizing activity indicators, but they are standardized indices rather than direct growth rates. The bridge model provides a way to map the activity index into the same unit as official GDP-component growth. It estimates the historical relationship between official y-o-y growth and the activity index before 2025Q2, then uses that relationship to predict what post-2025Q2 growth would have looked like based on the indicators.

The bridge model is:

$$y_t = \alpha + \beta t + \gamma f_t + \varepsilon_t,$$

where y_t is official y-o-y growth of household consumption or GFCF, f_t is the PCA-based activity index, and t is a linear time trend. The model is estimated only over the pre-2025Q2 sample.

The bridge gap measures the difference between official growth and indicator-implied growth. After estimating the pre-break relationship, the model generates fitted values for the post-2025Q2 period:

$$\hat{y}_t = \hat{\alpha} + \hat{\beta} t + \hat{\gamma} f_t.$$

The bridge gap is then calculated as:

$$\text{Gap}_t = y_t - \hat{y}_t.$$

A positive gap means that official growth is higher than the level implied by the activity indicators. A small gap suggests stronger consistency between official data and the independent indicators. A large positive gap suggests that the official growth acceleration is not fully mirrored by the indicators.

The interpretation should focus on the size and direction of the gap, not only statistical fit.

A high pre-break correlation or a high in-sample fit means that the index tracked the official series reasonably well before 2025Q2. But the key question is whether the same relationship continues after the candidate break. If official growth rises while the indicator-implied value does not, the bridge gap becomes evidence of weaker external validation.

OA3. Event-study design

The event study provides a market-based validation check. While the PCA and bridge-model exercises examine real-activity indicators, the event study asks whether financial markets reacted differently to GDP announcements after 2025Q2. The logic is that if markets viewed the stronger

GDP releases as credible positive news, the announcements might be associated with stronger equity returns, rupiah appreciation, or lower bond yields. If the reaction is weak, mixed, or points to rupiah pressure, the market-based validation is more limited.

The comparison is between previous non-COVID GDP announcements and post-2025Q2 GDP announcements. COVID-period announcements are excluded because market reactions during that period were likely dominated by extraordinary pandemic-related shocks. The post-2025Q2 group captures GDP announcements after the candidate break. The assets examined are the IDX Composite, BI spot USD/IDR, JISDOR, and 1-year and 10-year government bond yields.

Daily returns are used for equities and exchange rates, while daily yield changes are used for bonds. For equities and exchange rates, daily returns are calculated as:

$$r_{i,t} = 100 \times (\log P_{i,t} - \log P_{i,t-1}).$$

For the IDX Composite, a positive return means the stock market increased. For BI spot USD/IDR and JISDOR, a positive return means rupiah depreciation, because the exchange rate is measured as rupiah per US dollar. For government bonds, the outcome variable is the daily change in the 1-year or 10-year yield.

Abnormal returns compare the observed market movement with a normal pre-event benchmark. The normal benchmark is calculated from the estimation window before the announcement, typically from 60 to 30 trading days before the event. The abnormal return is:

$$AR_{i,t} = r_{i,t} - \bar{r}_{i,\text{estimation window}}.$$

For bond yields, the same logic is applied to yield changes rather than returns. This removes the average pre-event movement and isolates whether the event-window movement differs from the normal benchmark.

Cumulative abnormal returns capture market responses over wider event windows. The analysis considers the announcement-day abnormal return, $AR[0]$, and cumulative abnormal returns over windows such as:

$$CAR[-1, +1], CAR[-2, +2], CAR[-5, +5].$$

These wider windows are useful because markets may anticipate scheduled GDP releases or adjust gradually after the announcement. However, wider windows also come with a trade-off: they may capture more event-related adjustment, but they may also include unrelated news.

The main statistic is the post-minus-previous difference in market reactions. This difference asks whether post-2025Q2 GDP announcements generated stronger or weaker market responses than previous non-COVID announcements. The analysis is also repeated with global controls and cross-market domestic controls to check whether the results are driven by broader global financial conditions or simultaneous domestic market movements.

The event-study evidence is mixed and should be interpreted cautiously. Equity responses are somewhat more positive after post-2025Q2 GDP announcements, but the result weakens after adding controls. FX responses point more toward rupiah pressure than confidence-driven appreciation. Bond-yield responses are small and statistically weak. Overall, the event study does not provide a strong market-based validation signal for the post-2025Q2 GDP acceleration.

OA4. Domestic market-stress index

The domestic market-stress index summarizes adverse movements across several financial markets. Instead of examining each asset separately, the index combines information from equities, exchange rates, and bond yields. It is constructed from standardized IDX returns, JISDOR returns, and 10-year bond-yield changes:

$$\text{Stress}_t = -\text{IDX return}_t^z + \text{JISDOR return}_t^z + \Delta 10\text{Y yield}_t^z.$$

Lower stock returns increase the stress index, rupiah depreciation increases the stress index, and higher 10-year bond yields increase the stress index. Therefore, a higher value means a more adverse domestic market reaction.

The stress-index result does not show a broad-based increase in domestic financial-market stress. The estimated post-minus-previous difference is negative but statistically insignificant. This means that the constructed stress index is not higher after post-2025Q2 GDP announcements. The result should be interpreted carefully: it does not prove that market stress declined, but it does suggest that there is no clear evidence of a broad-based increase in domestic market stress around those GDP releases.

OA5. List of Variables

■ **TABLE A.1** Official GDP components

Variable	Component	Description	Frequency	Source
gdp	GDP aggregate	Real Gross Domestic Product at constant prices, seasonally adjusted; IDR billion.	Quarterly	Indonesia Statistic Office (BPS)
c	Household consumption	Real household final consumption expenditure at constant prices, seasonally adjusted; IDR billion.	Quarterly	Indonesia Statistic Office (BPS)
i	Gross fixed capital formation	Real gross fixed capital formation at constant prices, seasonally adjusted; IDR billion.	Quarterly	Indonesia Statistic Office (BPS)

■ **TABLE A.2** HHA I indicators (Household consumption activity index)

Variable	Component	Description	Frequency	Source
cci_present	Consumer Confidence	Consumer Confidence Index, present-situation sub-index.	Monthly	Central Bank of Indonesia
cci_expectations	Consumer Confidence	Consumer Confidence Index, expectations sub-index.	Monthly	Central Bank of Indonesia
retail_sales_real	Retail activity	Real Retail Sales Index.	Monthly	Central Bank of Indonesia
motor_vehicle_sales	Retail activity	Domestic wholesale motor vehicle sales; units.	Quarterly	Gabungan Industri Kendaraan Bermotor Indonesia (Gaikindo).
hh_motor_vehicle_loans	Household loans	Outstanding commercial bank loans to households for ownership of motor vehicles; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
housing_loans_idr	Household loans	Outstanding housing loans, all banks; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
bls_consumption_loans	BLS credit demand	Banking Lending Survey: demand for new consumption loans; weighted net balance.	Quarterly	Central Bank of Indonesia
bls_housing_property	BLS credit demand	BLS: demand for new consumption loans, housing and property sub-component; weighted net balance.	Quarterly	Central Bank of Indonesia
bls_motor_vehicle	BLS credit demand	BLS: demand for new consumption loans, motor vehicle sub-component; weighted net balance.	Quarterly	Central Bank of Indonesia
bls_credit_card	BLS credit demand	BLS: demand for new consumption loans, credit card sub-component; weighted net balance.	Quarterly	Central Bank of Indonesia

Variable	Component	Description	Frequency	Source
<i>BLS: Multi Purpose</i>	BLS credit demand	BLS: demand for new consumption loans, multi-purpose sub-component; weighted net balance.	Quarterly	Central Bank of Indonesia
<i>Value Added Tax revenue</i>	Consumption tax	Government domestic revenue from value-added tax; IDR (year-to-date).	Monthly	Ministry of Finance
<i>E-Commerce Transactions</i>	Digital consumption	Value of e-commerce transactions in Indonesia; IDR.	Monthly	Central Bank of Indonesia

■ **TABLE A.3** IAI indicators (Investment activity index)

Variable	Component	Description	Frequency	Source
investment_realization	Investment survey	Realized investment, amount of investment sub-question; weighted net balance; percent.	Quarterly	Central Bank of Indonesia
capacity_utilization	Capacity	Production capacity utilization rate; percent.	Quarterly	Central Bank of Indonesia
business_activity	Business conditions	Realized business activity; weighted net balance.	Quarterly	Central Bank of Indonesia
pmi	Manufacturing	Manufacturing PMI for Indonesia.	Monthly	S&P Global
cement_consumption	Construction	Domestic cement consumption; thousand tonnes.	Monthly	Asosiasi Semen Indonesia (ASI / Indonesian Cement Association).
bank_investment_loans	Bank credit (stock)	Outstanding investment loans, commercial and rural banks combined; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
bank_working_capital_loans	Bank credit (stock)	Outstanding working capital loans, commercial and rural banks combined; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
capital_goods_imports	Capital imports	Capital goods imports, CIF; volume series.	Monthly	Indonesia Statistics Office (BPS)

Variable	Component	Description	Frequency	Source
bls_investment_loans	BLS credit demand	BLS: demand for new loans, investment loans sub-component; weighted net balance.	Quarterly	Indonesia Financial Service Authority (OJK)
bls_working_capital	BLS credit demand	BLS: demand for new loans, working capital sub-component; weighted net balance.	Quarterly	Indonesia Financial Service Authority (OJK)
<i>Prompt Manufacturing Index</i>	Manufacturing	Prompt Manufacturing Index.	Monthly	Central Bank of Indonesia
<i>Prompt Manufacturing Index: Inventory</i>	Manufacturing	PMI-BI inventory sub-index; diffusion index.	Monthly	Central Bank of Indonesia
<i>MSME Credit: Industry</i>	Business credit	Outstanding credit to MSMEs by industrial sector; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
<i>Wholesale & Retail Trade Loans</i>	Bank credit, sector	Outstanding commercial and rural bank loans to wholesale and retail trade sector (incl. motor-vehicle repair); IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
<i>MSME Wholesale & Retail Credit</i>	Bank credit, sector	MSME credit to wholesale and retail trade sector; IDR billion.	Monthly	Indonesia Financial Service Authority (OJK)
<i>BLS Demand for New Loans (aggregate)</i>	BLS credit demand	Banking Lending Survey: headline aggregate demand for new loans; weighted net balance.	Quarterly	Central Bank of Indonesia
<i>CEIC Leading Indicator</i>	Composite leading indicator	CEIC's proprietary composite leading indicator for Indonesia; index number.	Monthly	CEIC
<i>Exports: fob: Volume</i>	External demand	Total merchandise exports, fob; volume series.	Monthly	Indonesia Statistic Office (BPS)

Variable	Component	Description	Frequency	Source
<i>Raw/Auxiliary Goods Imports</i>	Industrial inputs	Raw and auxiliary goods imports, CIF; volume series.	Monthly	Indonesia Statistics Office (BPS)
<i>Industrial Production Index (IPI)</i>	Industrial production	Industrial Production Index; 2010 = 100.	Quarterly	Indonesia Statistics Office (BPS)
